

Cognitive Orgies III: Interspecies Home Viewing

Our project aimed to create an experience when humans are assessed if they are fit into a space and can live together with other species. Within the collaboration I was responsible for the technical implementation, therefore, my individual reflection will focus on this aspect of the project.

The aim of the reflection is to give a high-level overview on the implemented installation tech concept, and provide critical observations how we can improve the design and crafting of such installation.

The Setup

Building Block	Learning & Improvement Ideas
1 Hardware	Considering the complexity of the installation we used simple hardware elements. To achieve better experience, desolve constraints (ie. bluetooth range), the improvement of the hardware pieces is needed - for example: professional sound and camera system.
2 Real-time caption and transcript	For a better observation experience real-time voice caption is advised. Currently, due to the voice quality, understanding the events in the Experiment Room could be challenging.
3 Video footage as input	Going further with the behaviour assessment method, incorporating video inputs - replacing human data capturing - can take the assessment and the surveillance experience to the next level.
4 Using sensors	Enriching the data capturing with sensors can give us further assessment criteria. Heat and movement sensors can give valuable information on how the subject behaved within the space.
5 Design method	Based on my latest interaction with audiovisual artists, one of my biggest learning was how much I skip the storyboarding in my design process. It is an important method that can help envisioning experience and sequence of steps.
